Best Choices for Regularization Parameters in Learning Theory:
On the Bias-Variance Problem

1 Introduction

The goal of learning theory (and a goal in some other contexts as well) is to find an approximation of a function \( f_{\rho} : X \to Y \) known only through a set of pairs \( z = (x_i, y_i)_{i=1}^m \) drawn from an unknown probability measure \( \rho \) on \( X \times Y \) (\( f_{\rho} \) is the “regression function” of \( \rho \)).

An approach championed by Poggio (see e.g. [5]) with ideas going back to Ivanov [7] and Tikhonov [13] is to minimize

\[
\frac{1}{m} \sum_{i=1}^{m} (f(x_i) - y_i)^2 + \gamma \| Af \|^2_{L^2_\rho(X)}
\]

where \( A \) is an differential operator and \( L^2_\rho(X) \) is the Hilbert space of square integrable functions on \( X \) with measure \( \rho_X \) on \( X \) defined via \( \rho \). See [4] (in the sequel

Also, the second named author expresses his appreciation to City University of Hong Kong for supporting his visit there in December 2001, when this paper was written.

1AMS classification: 68T05, 62J02.
denoted by $[CS]$) for background on this and, even more importantly, for results used here.

This minimization is well-conditioned and solved by straightforward finite dimensional least squares linear algebra (see Theorem 1 below) to yield $f_{\gamma,z} : X \to Y$. The problem is posed: \textit{How good an approximation is $f_{\gamma,z}$ to $f_\rho$, or measure the error $\int_X (f_{\gamma,z} - f_\rho)^2$? and What is the best choice of $\gamma$ to minimize this error?}

Our goal in this report is to give some answers to these questions.

\textbf{Main result.} \textit{We exhibit, for each $m \in \mathbb{N}$ and $\delta \in [0,1)$, a function}

$$E_{m,\delta} = E : \mathbb{R}^+ \to \mathbb{R}$$

\textit{such that, for all $\gamma > 0$,}

$$\int_X (f_{\gamma,z} - f_\rho)^2 \leq E(\gamma)$$

\textit{with confidence $1 - \delta$. There is a unique minimizer of $E(\gamma)$ which is found by an easy algorithm to yield the “best” regularization parameter $\gamma = \gamma^*$.}

The bound $E(\gamma)$ found is a natural one, a bound which flows from the hypotheses and thus yields a $\gamma^*$ which could be useful in the algorithmics for $f_{\gamma,z}$. Of course, $\gamma^*$ depends on the number of examples $m$, confidence $1 - \delta$, as well as the operator $A$ and a simple invariant of $\rho$.

\section{RKHS and Regularization Parameters}

Let $X$ be a compact domain or a manifold in Euclidean space and $Y = \mathbb{R}$ (one can extend all what follows to $Y = \mathbb{R}^k$ with $k \in \mathbb{N}$). Let $\rho$ be a Borel probability measure on $Z = X \times Y$.

For every $x \in X$, let $\rho(y|x)$ be the conditional (w.r.t. $x$) probability measure on $Y$ and $\rho_X$ be the marginal probability measure on $X$, i.e. the measure on $X$ defined by $\rho_X(S) = \rho(\pi^{-1}(S))$ where $\pi : X \times Y \to X$ is the projection. Notice that $\rho$, $\rho(y|x)$ and $\rho_X$ are related as follows. For every integrable function $\varphi : X \times Y \to \mathbb{R}$ a version of Fubini’s Theorem states that

$$\int_{X \times Y} \varphi(x,y) \, d\rho = \int_X \left( \int_Y \varphi(x,y) \, d\rho(y|x) \right) \, d\rho_X.$$

This “breaking” of $\rho$ into the measures $\rho(y|x)$ and $\rho_X$ corresponds to looking at $Z$ as a product of an input domain $X$ and an output set $Y$.

Define $f_\rho : X \to Y$ by

$$f_\rho(x) = \int_Y y \, d\rho(y|x).$$

The function $f_\rho$ is called the \textit{regression function} of $\rho$. For each $x \in X$, $f_\rho(x)$ is the average of the $y$ coordinate of $\{x\} \times Y$. 

2
In what follows we assume \( f_\rho \in L_\rho^2(X) \) is bounded. We also assume that
\[
M_\rho = \inf \{M \geq 0 \mid (x, y) \in \mathbb{Z} \mid |y - f_\rho(x)| \geq M \} \text{ has measure zero}
\]
is finite. Note that this implies that
\[
|y| \leq M = \max\{|\|f_\rho\|_\infty + M_\rho, 1\}
\]
almost surely.

Recall, \( \|f\| \) denotes, unless otherwise specified, the norm of \( f \) in \( L_\rho^2(X) \). Let \( K \) be a Mercer kernel. That is, \( K : X \times X \to \mathbb{R} \) is continuous, symmetric and \( K \) is positive semidefinite, i.e. for all finite sets \( \{x_1, \ldots, x_k\} \subset X \) the \( k \times k \) matrix \( K[x] \) whose \((i, j)\) entry is \( K(x_i, x_j) \) is positive semidefinite. Then (cf. Chapter III of [CS]) \( K \) determines a linear operator \( L_K : L_\rho^2(X) \to \mathcal{C}(X) \) given by
\[
(L_K f)(x) = \int K(x, t)f(t)dt
\]
which is well-defined, positive, and compact. In addition, there exists a Hilbert space \( \mathcal{H}_K \) of continuous functions on \( X \) (called reproducing kernel Hilbert space, RKHS for short) associated to \( K \) and \( X \) and independent of \( \rho \) such that the linear map \( L_K^{1/2} \) is a Hilbert isomorphism between \( L_\rho^2(X) \) and \( \mathcal{H}_K \). Here \( L_K^{1/2} \) denotes the square root of \( L_K \), i.e. the only linear operator satisfying \( L_K^{1/2} \circ L_K^{1/2} = L_K \). Thus, we have the following diagram
\[
\begin{array}{ccc}
L_\rho^2(X) & \xrightarrow{L_K^{1/2}} & \mathcal{C}(X) \\
\downarrow L_K^{1/2} & \approx & \downarrow \mathcal{I}_K \\
\mathcal{H}_K & & \\
\end{array}
\]
where we write \( L_K^{1/2} \) to emphasize that the target is \( \mathcal{C}(X) \) and \( \mathcal{I}_K \) denotes the inclusion. If \( K \) is \( \mathcal{C}^\infty \) then \( \mathcal{I}_K \) is compact. In the sequel, \( K \) denotes a \( \mathcal{C}^\infty \) Mercer kernel, and \( \| \cdot \|_K \) the norm in \( \mathcal{H}_K \).

Let \( z = (z_1, \ldots, z_m) \) with \( z_i = (x_i, y_i) \in X \times Y \) for \( i = 1, \ldots, m \). We also write \( x = (x_1, \ldots, x_m) \), \( y = (y_1, \ldots, y_m) \). Note that since \( K \) is a Mercer kernel \( K[x] \) is positive semidefinite.

For \( \gamma > 0 \) let \( \Phi(\gamma) \) and \( \Phi_z(\gamma) \) be the problems respectively
\[
\min \int_X (f(x) - y)^2 + \gamma \|f\|_K^2 \\
\text{s.t.} \quad f \in \mathcal{H}_K
\]
and
\[
\min \frac{1}{m} \sum_{i=1}^m (f(x_i) - y_i)^2 + \gamma \|f\|_K^2 \\
\text{s.t.} \quad f \in \mathcal{H}_K.
\]
For $x \in X$, let $K_x : X \to \mathbb{R}$ be given by $K_x(t) = K(x,t)$.

**Theorem 1** For all $\gamma > 0$, the minimizers $f_\gamma$ and $f_{\gamma,z}$ of $\Phi(\gamma)$ and $\Phi_z(\gamma)$ respectively exist and are unique. In addition

$$f_\gamma = (\text{Id} + \gamma L_K^{-1})^{-1} f_\rho$$

and $f_{\gamma,z}$ is given by

$$f_{\gamma,z}(x) = \sum_{i=1}^{m} a_i K(x,x_i)$$

where $a = (a_1, \ldots, a_m)$ is the unique solution of the well-posed linear system in $\mathbb{R}^m$

$$(\gamma m \text{Id} + K[x])a = y.$$ 

Finally, for $f = \sum_{i=1}^{m} a_i K_{x_i}$ we have $\|f\|_K^2 = a^T K[x] a$.

**Proof.** See Propositions 7 and 8 and Theorem 2 in Chapter III of [CS] and its references, and [5] and its references.

3 Estimating the Confidence

Define, for $f \in \ell_\rho^2(X)$, its error

$$\mathcal{E}(f) = \int_Z (f(x) - y)^2$$

and, given a sample $z \in Z^m$, its empirical error

$$\mathcal{E}_z(f) = \frac{1}{m} \sum_{i=1}^{m} (f(x_i) - y_i)^2.$$

Note that from the equality $\mathcal{E}(f_{\gamma,z}) = \mathcal{E}(f_{\gamma,z}) - \mathcal{E}(f_\gamma) + \mathcal{E}(f_\gamma)$ we deduce

$$\mathcal{E}(f_{\gamma,z}) \leq |\mathcal{E}(f_{\gamma,z}) - \mathcal{E}(f_\gamma)| + \mathcal{E}(f_\gamma)$$

We will call the first term in the right-hand side the sample error (this use of the expression slightly differs from the one in [CS]) and the second, the approximation error. Note that the sample error is a random variable on the space $Z^m$. In this section we will bound the confidence for the sample error to be small enough. The main result is Theorem 2 below.

For $r > 0$ let $B_r = \{ f \in \mathcal{H}_K \mid \|f\|_K \leq r \}$ and $\mathcal{H}(r) = \overline{I_K(B_r)}$. Notice that this is a compact subset of $\mathcal{C}(X)$ so that, for every $\eta$, the covering number

$$\mathcal{N}(\mathcal{H}(r), \eta) = \min\{ s \in \mathbb{N} \mid \exists s \text{ closed balls of radius } \eta \text{ in } \mathcal{C}(X) \text{ covering } \mathcal{H}(r) \}$$

4
is finite. Also, let
\[ C_K = \max \left\{ 1, \sup_{x,t \in \mathcal{X}} |K(x,t)| \right\} \]
and
\[ R_\gamma = \frac{\sqrt{C_K} \|f_\rho\|_\infty}{\gamma}, \quad \text{and} \quad r_\gamma = \frac{\sqrt{C_K} M}{\gamma}. \]

**Theorem 2** For all \( \gamma, \varepsilon > 0 \),
\[
\text{Prob} \left\{ |\mathcal{E}(f_\gamma) - \mathcal{E}(f_{\gamma,x})| \leq \varepsilon \right\} \geq 1 - 4 \left[ m + \mathcal{N} \left( \mathcal{H}(r_\gamma), \sqrt{\frac{\varepsilon \gamma}{32 M (\gamma + C_K)}} \right) \right]^m e^{-\frac{m^2}{2} \frac{\varepsilon^2}{4}}.
\]

The idea towards the proof of Theorem 2 is to write
\[
\mathcal{E}(f_\gamma) - \mathcal{E}(f_{\gamma,x}) = \mathcal{E}(f_\gamma) - \mathcal{E}_x(f_\gamma) + \mathcal{E}_x(f_\gamma) - \mathcal{E}_x(f_{\gamma,x}) + \mathcal{E}_x(f_{\gamma,x}) - \mathcal{E}(f_{\gamma,x})
\]
from which it follows that
\[
|\mathcal{E}(f_\gamma) - \mathcal{E}(f_{\gamma,x})| \leq |\mathcal{E}(f_\gamma) - \mathcal{E}_x(f_\gamma)| + |\mathcal{E}_x(f_\gamma) - \mathcal{E}_x(f_{\gamma,x})| + |\mathcal{E}_x(f_{\gamma,x}) - \mathcal{E}(f_{\gamma,x})|.
\]

We first, see Proposition 1 below, bound (with high confidence) the first and last terms in the sum above. Towards this end we give bounds on \( \|f_\gamma\|_K, \|f_{\gamma,x}\|_K, \|f_\gamma\|_\infty \), and \( \|f_{\gamma,x}\|_\infty \).

**Lemma 1** For all \( \gamma > 0 \)
\[
\|f_\gamma\|_K \leq R_\gamma.
\]

**Proof.** Let \( f_\rho = \sum c_i \phi_i \). Then
\[
f_\gamma = \sum_{i=1}^\infty \left( 1 + \frac{\gamma}{\lambda_i} \right)^{-1} c_i \phi_i = \sum_{i=1}^\infty \left( \frac{\lambda_i}{\gamma + \lambda_i} \right) c_i \phi_i
\]
and therefore
\[
\|f_\gamma\|_K^2 = \sum_{i=1}^\infty \frac{\lambda_i}{(\gamma + \lambda_i)^2} c_i^2 \leq \frac{1}{\gamma^2} \max_{i \geq 1} \lambda_i \|f_\rho\|_2^2.
\]

\[ \Box \]
Lemma 2 For all $\gamma > 0$
\[ \| f_{\gamma,z} \|_K \leq r_\gamma. \]

Proof. Since $f_{\gamma,z} = \sum a_i K_{x_i}$ we have $\| f_{\gamma,z} \|_K^2 = a^T K[x] a$. Also, since $a = (\gamma m \text{Id} + K[x])^{-1} y$ it follows that
\[ \| a \| \leq \| y \| \| (\gamma m \text{Id} + K[x])^{-1} \| \leq \sqrt{m} M \frac{1}{\gamma m} = \frac{M \sqrt{m}}{\gamma} \]
where $\| a \|$ and $\| y \|$ refer to the Euclidean norm in $\mathbb{R}^m$. Therefore
\[ \| f_{\gamma,z} \|_K^2 \leq \| a \|^2 \| K[x] \| \leq \frac{M^2}{\gamma^2 m} C_K m = \frac{M^2}{\gamma^2} C_K \]
where $\| K[x] \|$ denotes the operator norm of $K[x] : \mathbb{R}^m \to \mathbb{R}^m$ with respect to the Euclidean norm in both domain and target space and we have used that, since each entry of $K[x]$ is bounded in absolute value by $C_K$, $\| K[x] \| \leq C_K m$.

Corollary 1 For all $\gamma > 0$, $\| f_{\gamma} \|_\infty \leq \frac{C_K \| f_0 \|_\infty}{\gamma}$ and $\| f_{\gamma,z} \|_\infty \leq \frac{C_K M}{\gamma}$. 

Proof. By Theorem 2 in Chapter III of [CS], $\| I_K \| \leq \sqrt{C_K}$.

Remark 1 Note that for all $\gamma > 0$, $r_\gamma \geq R_\gamma$.

Proposition 1 For all $\varepsilon, \gamma > 0$,

(i)
\[ \operatorname{Prob}_{z \in Z^m} \{ |\mathcal{E}(f_{\gamma}) - \mathcal{E}_z(f_{\gamma})| \leq \varepsilon \} \geq 1 - N \left( \mathcal{H}(R_\gamma), \frac{\varepsilon \gamma}{8M(\gamma + C_K)} \right) 2e^{-\frac{m \varepsilon^2 \gamma^4}{8M^2(\gamma + C_K)^3}}. \]

(ii)
\[ \operatorname{Prob}_{z \in Z^m} \{ |\mathcal{E}(f_{\gamma,z}) - \mathcal{E}_z(f_{\gamma,z})| \leq \varepsilon \} \geq 1 - N \left( \mathcal{H}(R_\gamma), \frac{\varepsilon \gamma}{8M(\gamma + C_K)} \right) 2e^{-\frac{m \varepsilon^2 \gamma^4}{8M^2(\gamma + C_K)^3}}. \]

Proof. We use Theorem B of [CS] but proved with Hoeffding’s inequality instead of Bernstein’s. This yields, for a compact subset $\mathcal{H}$ of $\mathcal{C}(X)$ such that $|f(x)-y| \leq M$ a.e. for all $f \in \mathcal{H}$, the uniform estimate
\[ \operatorname{Prob}_{z \in Z^m} \left\{ \sup_{f \in \mathcal{H}} |\mathcal{E}(f) - \mathcal{E}_z(f)| \leq \varepsilon \right\} \geq 1 - N \left( \mathcal{H}, \frac{\varepsilon}{8M} \right) 2e^{-\frac{m \varepsilon^2}{8M^2}}. \]

For (i) use this estimate applied to $\mathcal{H} = \mathcal{H}(R_\gamma)$, and
\[ M = \| f_{\gamma} \|_\infty + M_0 + \| f_0 \|_\infty \leq \frac{C_K \| f_0 \|_\infty}{\gamma} + M \leq \frac{M(\gamma + C_K)}{\gamma}. \]
and note that
\[
\text{Prob} \left\{ \left| \mathcal{E}(f_{\gamma}) - \mathcal{E}_x(f_{\gamma}) \right| \leq \varepsilon \right\} \geq \text{Prob} \left\{ \sup_{f \in \mathcal{H}(R_{\gamma})} \left| \mathcal{E}(f) - \mathcal{E}_x(f) \right| \leq \varepsilon \right\}.
\]

A similar proof, now with \( \mathcal{H} = \mathcal{H}(r_{\gamma}) \), and
\[
M = \|f_{\gamma}\|_{\infty} + M_p + \|f_p\|_{\infty} \leq \frac{C_K M}{\gamma} + M = \frac{M(\gamma + C_K)}{\gamma},
\]
yields (ii).

We now proceed with the middle term \( |\mathcal{E}_x(f_{\gamma}) - \mathcal{E}_x(f_{\gamma,x})| \).

In what follows, for \( f : X \to \mathbb{R} \) and \( x \in X^m \), we denote by \( f[x] \) the point \((f(x_1), \ldots, f(x_m)) \in \mathbb{R}^m \). Also, if \( v \in \mathbb{R}^m \), we denote \( \|v\|_{\max} = \max\{|v_1|, \ldots, |v_m|\} \).

**Proposition 2** For all \( \gamma, \varepsilon > 0 \),
\[
\text{Prob} \left\{ \|f_{\gamma}[x] - f_{\gamma,x}[x]\|_{\max} \leq 2\varepsilon \right\} \geq 1 - 4me^{-\frac{m\varepsilon^2}{8M^2\gamma^2 + C_K}}.
\]

**Proof of Theorem 2.** Recall,
\[
|\mathcal{E}(f_{\gamma}) - \mathcal{E}(f_{\gamma,x})| \leq |\mathcal{E}(f_{\gamma}) - \mathcal{E}_x(f_{\gamma})| + |\mathcal{E}_x(f_{\gamma}) - \mathcal{E}_x(f_{\gamma,x})| + |\mathcal{E}_x(f_{\gamma,x}) - \mathcal{E}(f_{\gamma,x})|.
\]
The first and last terms are each bounded by \( \varepsilon \) with probabilities at least
\[
1 - \mathcal{N}\left( \mathcal{H}(r_{\gamma}), \frac{\varepsilon \gamma}{8M(\gamma + C_K)} \right) 2e^{-\frac{m\varepsilon^2}{8M^2\gamma^2 + C_K}}
\]
by Proposition 1 and the fact that \( r_{\gamma} \geq R_{\gamma} \). For the middle term note that
\[
|\mathcal{E}_x(f_{\gamma}) - \mathcal{E}_x(f_{\gamma,x})| = \frac{1}{m} \left| \sum_{i=1}^m (f_{\gamma}(x_i) - y_i) - \sum_{i=1}^m (f_{\gamma,x}(x_i) - y_i) \right|
\leq \frac{1}{m} \sum_{i=1}^m |f_{\gamma}(x_i) - f_{\gamma,x}(x_i)|
\leq \|f_{\gamma}[x] - f_{\gamma,x}[x]\|_{\max}.
\]
Now apply Proposition 2 to bound this term by \( 2\varepsilon \) with probability at least
\[
1 - 4me^{-\frac{m\varepsilon^2}{8M^2\gamma^2 + C_K}}
\]
and the conclusion follows by noting that \( 2C_2^2 M^2(\gamma + C_K)^2 \leq 8M^4(\gamma + C_K)^4 \) and by replacing \( \varepsilon \) by \( \varepsilon/4 \). \( \square \)
It only remains to prove Proposition 2. Towards this end, recall, Hoeffding’s inequality states that if $\xi$ is a random variable on a probability space $Z$ bounded almost everywhere by $M$ with mean $\mu$ then

$$\text{Prob}_{z \in Z^n}\left\{ \left| \frac{1}{m} \sum_{i=1}^{m} \xi(z_i) - \mu \right| \leq \varepsilon \right\} \geq 1 - 2e^{-\frac{m\varepsilon^2}{2M^2}}. $$

**Lemma 3** For all $\gamma, \varepsilon > 0$ and all $t \in X$,

$$\text{Prob}_{z \in Z^n}\left\{ \left| \frac{1}{m\gamma} \sum_{i=1}^{m} K(x_i, t)(f_\rho(x_i) - y_i) \right| \leq \varepsilon \right\} \geq 1 - 2e^{-\frac{\varepsilon^2}{2||f_\rho||_\infty^2 + \sqrt{C_K R_\gamma}}}.$$

**Proof.** Consider the random variable

$$z \mapsto \frac{1}{\gamma} K(x, t)(f_\rho(x) - y).$$

It is almost everywhere bounded by $\frac{1}{\gamma} C_K M_\rho$. Its mean is 0 since, by Fubini’s Theorem

$$\int Z \frac{1}{\gamma} K(x, t)(f_\rho(x) - y) = \int X \frac{1}{\gamma} K(x, t) \left( \int Y f_\rho(x) - y d\rho(y|x) \right) d\rho_x$$

and the inner integral is 0 by definition of $f_\rho$. Now apply Hoeffding’s inequality.

**Lemma 4** For all $\gamma, \varepsilon > 0$ and all $t \in X$,

$$\text{Prob}_{z \in Z^n}\left\{ \left| f_\gamma(t) - \frac{1}{m\gamma} \sum_{i=1}^{m} K(x_i, t)(f_\rho(x_i) - f_\gamma(x_i)) \right| \leq \varepsilon \right\} \geq 1 - 2e^{-\frac{\varepsilon^2}{2||f_\rho||_\infty^2 + \sqrt{C_K R_\gamma}}}.$$

**Proof.** By Theorem 1,

$$f_\gamma = (\text{Id} + \gamma L_K^{-1})^{-1} f_\rho \Rightarrow f_\gamma + \gamma L_K^{-1} f_\gamma = f_\rho$$

$$\Rightarrow L_K f_\gamma + \gamma f_\gamma = L_K f_\rho$$

$$\Rightarrow f_\gamma = \frac{1}{\gamma} L_K (f_\rho - f_\gamma)$$

$$\Rightarrow f_\gamma(t) = \int X \left( \frac{1}{\gamma} K(x, t)(f_\rho(x) - f_\gamma(x)) \right) d\rho_x.$$

The function inside the last integral can be thus considered a random variable on $X$ with mean $f_\gamma(t)$. It is bounded by $\frac{C_K}{\gamma}(||f_\rho||_\infty + \sqrt{C_K R_\gamma})$. Again, apply Hoeffding’s inequality.
Lemma 5 For all $\gamma, \varepsilon > 0$,

$$\text{Prob}_{x \in \mathbb{Z}^m} \left\{ \left\| \left( \text{Id} + \frac{K[x]}{\gamma m} \right) f_{\gamma, x} - \frac{K[x]y}{\gamma m} \right\|_{\text{max}} \leq 2\varepsilon \right\} \geq 1 - 4me^{-\frac{m\varepsilon^2}{2C_K^2M^2(\gamma + C_K)^2}}.$$

Proof. From Lemmas 3 and 4 it follows that, with a probability at least

$$1 - 2 \left( e^{-\frac{m\varepsilon^2}{2(C_KM^2)^2}} + e^{-\frac{m\varepsilon^2}{2C_K^2\|f\|_\infty^2 + \sqrt{C_K}M\gamma^2}} \right)$$

for every $t \in X$,

$$\left| f_{\gamma}(t) + \frac{1}{m\gamma} \sum_{i=1}^{m} K(x_i, t)(f_{\gamma}(x_i) - y_i) \right| \leq 2\varepsilon.$$

Note that, since

$$\max \{ M_p, \| f_p \|_\infty + \sqrt{C_K}R_\gamma \} \leq M + \sqrt{C_K}r_\gamma = \frac{M(\gamma + C_K)}{\gamma}$$

the confidence above is at least

$$1 - 4e^{-\frac{m\varepsilon^2}{2C_K^2M^2(\gamma + C_K)^2}}.$$ 

Applying this to $t = x_1, \ldots, x_m$ and writing the $m$ resulting inequalities in matrix form we obtain that, with confidence at least the one in the statement,

$$\left\| f_{\gamma}[x] + \frac{1}{m\gamma}K[x]f_{\gamma}[x] - \frac{1}{m\gamma}K[x]y \right\|_{\text{max}} \leq 2\varepsilon.$$

Lemma 6 For all $\gamma, \varepsilon > 0$,

$$\left( \text{Id} + \frac{K[x]}{\gamma m} \right) f_{\gamma, x}(x) = \frac{K[x]y}{\gamma m}.$$

Proof. In Proposition 8, Chapter III of [CS] it is shown that

$$f_{\gamma, x}(t) = \sum_{i=1}^{m} \frac{y_i - f_{\gamma, x}(x_i)}{\gamma m} K(x_i, t)$$

$$\Rightarrow \gamma m f_{\gamma, x}(t) = \sum_{i=1}^{m} (y_i - f_{\gamma, x}(x_i)) K(x_i, t)$$

$$\Rightarrow \gamma m f_{\gamma, x}(t) + \sum_{i=1}^{m} f_{\gamma, x}(x_i) K(x_i, t) = \sum_{i=1}^{m} y_i K(x_i, t).$$
Applying this equality for \( t = x_1, \ldots, x_m \) and writing the resulting \( m \) equalities in matrix form we obtain

\[
\gamma_m f_{\gamma,x}[x] + f_{\gamma,x}[x]K[x] = K[x]y
\]

from which the statement follows. \( \square \)

**Proof of Proposition 2.** From Lemmas 5 and 6 it follows that

\[
\left\| \left( \text{Id} + \frac{K[x]}{\gamma_m} \right) f_{\gamma}[x] - \left( \text{Id} + \frac{K[x]}{\gamma_m} \right) f_{\gamma,x}[x] \right\|_{\text{max}} \leq 2\varepsilon
\]

i.e.

\[
\left\| \left( \text{Id} + \frac{K[x]}{\gamma_m} \right) (f_{\gamma}[x] - f_{\gamma,x}[x]) \right\|_{\text{max}} \leq 2\varepsilon
\]

with the stated confidence. The result now follows since \( \frac{K[x]}{\gamma_m} \) is positive definite and therefore \( \left\| \left( \text{Id} + \frac{K[x]}{\gamma_m} \right)^{-1} \right\| \geq 1. \) \( \square \)

### 4 Estimating the Sample Error

The expression \( \| \mathcal{E}(f_{\gamma}) - \mathcal{E}(f_{\gamma,x}) \| \) is called the **sample error** (of \( f_{\gamma,x} \)). In the previous section we estimated the confidence of obtaining a small sample error when the sample size \( m \) and an error bound \( \varepsilon \) are given. In this section we will fix a confidence \( 1 - \delta \) and a sample size \( m \) and obtain bounds for the sample error.

**Lemma 7** Let \( c_1, c_2 > 0 \) and \( s > q > 0 \). Then the equation

\[
x^s - c_1x^q - c_2 = 0
\]

has a unique positive zero \( x^* \). In addition

\[
x^* \leq \max \left\{ \frac{1}{2s}, \frac{1}{2} \right\}.
\]

**Proof.** Let \( \varphi(x) = x^s - c_1x^q - c_2 \). Then, taking the derivative with respect to \( x \), \( \varphi'(x) = sx^{s-1} - qc_1x^{q-1} = x^{q-1}(sx^{s-q} - qc_1) \). Thus

\[
\varphi'(x) = 0 \iff x^{s-q} = \frac{qc_1}{s}
\]

and this derivative has a unique positive zero. The first statement follows since \( \varphi(0) < 0 \), \( \varphi(0^+) \leq 0 \) and \( \varphi(x) \to +\infty \) when \( x \to +\infty \).
The second statement is a well-known bound (see [10, Theorem 4.2 (iv)]).

\(\square\)

**Remark 2** Note that, given \(c_1, c_2, s\) and \(t\) one can efficiently compute (a good approximation of) \(x^*\) using algorithms such as Newton’s method.

By Theorem 2, the sample error \(\varepsilon\) satisfies, with confidence \(1 - \delta\),

\[
4mN\left(\mathcal{H}(r_{\gamma}), \frac{\varepsilon \gamma}{32M(\gamma + C_K)}\right) e^{-\frac{m e^2 \gamma^4}{128 M^4(\gamma + C_K)^4}} \geq \delta
\]

i.e.

\[
\frac{m e^2 \gamma^4}{128 M^4(\gamma + C_K)^4} - \ln\left(\frac{4m}{\delta}\right) - \ln N\left(\mathcal{H}(r_{\gamma}), \frac{\varepsilon \gamma}{32M(\gamma + C_K)}\right) \leq 0. \tag{1}
\]

Now we recall (cf. Section 6 in Chapter I of [CS]) that, for every \(t < 2\) there exists a constant \(C_t\) independent of \(\varepsilon\) and \(\gamma\), such that

\[
\ln N\left(\mathcal{H}(r_{\gamma}), \frac{\varepsilon \gamma}{32M(\gamma + C_K)}\right) \leq \left(r_{\gamma} C_t 32M(\gamma + C_K) / \varepsilon \gamma\right)^t \leq \left(\frac{32C_t M^2(\gamma + C_K)^2}{\varepsilon \gamma^2}\right)^t
\]

(a different bound appears in [15]). Note, in the last inequality we replaced \(r_{\gamma}\) by its definition and used that \(\sqrt{C_K} \leq (C_K + \gamma)\). Using this bound for the covering number, inequality (1) becomes

\[
\frac{m e^2 \gamma^4}{128 M^4(\gamma + C_K)^4} - \ln\left(\frac{4m}{\delta}\right) - \left(\frac{32C_t M^2(\gamma + C_K)^2}{\varepsilon \gamma^2}\right)^t \leq 0.
\]

Write

\[
v = \frac{\varepsilon \gamma^2}{32M^2(\gamma + C_K)^2}.
\]

Then the inequality above takes the form

\[
\alpha_0 v^2 - c_1 - c_2 v^{-t} \leq 0 \quad \tag{2}
\]
where \( c_0 = \frac{m}{4} \), \( c_1 = \ln \left( \frac{4m}{\delta} \right) \), \( c_2 = C_t^t \), the \( t \)th power of \( C_t \). Note that one could fix, for example, \( t = 1 \).

Now take the equality in (2) to obtain the equation
\[
\varphi(v) = v^{t+2} - \frac{c_1}{c_0} v^t - \frac{c_2}{c_0} = 0
\]
and note that this equation has only one positive zero by Lemma 7. Let \( v^*(m, \delta) \) be this solution. Then, also by Lemma 7,
\[
v^*(m, \delta) \leq \left\{ \left( \frac{8 \ln(4m) - \ln(\delta)}{m} \right)^{1/2}, \left( \frac{8C_t^t}{m} \right)^{t+2} \right\}
\]
and
\[
\varepsilon = \frac{32 M^2 (\gamma + C_K)^2}{\gamma^2} v^*(m, \delta)
\]
and we can conclude stating the following result.

**Theorem 3** Given \( m \geq 1 \) and \( 0 < \delta \leq 1 \), for all \( \gamma > 0 \), the expression
\[
\mathcal{S}(\gamma) = \frac{32 M^2 (\gamma + C_K)^2}{\gamma^2} v^*(m, \delta)
\]
bounds the sample error with confidence at least \( 1 - \delta \). \( \square \)

5 **Choosing the optimal \( \gamma \)**

We now focus on the approximation error \( \mathcal{E}(f_\gamma) \). To do so, we first apply part (1) of Theorem 3, Chapter II in [CS] with \( H = L^2_\rho(X) \), \( s = 1 \), \( A = L^{1/2}_K \), and \( a = f_\rho \), and use that \( \|L^{-1/2}_K f\| = \|f\|_K \) to obtain that, for \( 0 < \theta < 1 \) (e.g., for \( \theta = 1/2 \)),
\[
\min_{f \in L^2_\rho(X)} (\|f - f_\rho\|^2 + \gamma \|f\|^2_K) \leq \gamma^\theta \|L^{-\theta/2}_K f_\rho\|^2.
\]
Since the minimum above is attained at \( f_\gamma \) we deduce
\[
\|f_\gamma - f_\rho\|^2 + \gamma \|f_\gamma\|^2_K \leq \gamma^\theta \|L^{-\theta/2}_K f_\rho\|^2.
\]
A basic result in [CS] (Proposition 1, Chapter I) states that, for all \( f \in L^2_\rho(X) \),
\[
\mathcal{E}(f) = \int_X (f - f_\rho)^2 + \sigma^2_\rho
\]
where \( \sigma^2_\rho \) is a non-negative quantity depending only on \( \rho \). Therefore the approximation error \( \mathcal{E}(f_\gamma) \) is bounded by \( \mathcal{S}(\gamma) + \sigma^2_\rho \), where
\[
\mathcal{S}(\gamma) = \gamma^\theta \|L^{-\theta/2}_K f_\rho\|^2.
\]
Proof of the Main Result. Let

$$E(\gamma) = \mathcal{A}(\gamma) + \mathcal{J}(\gamma).$$

Recall

$$\mathcal{E}(f_{\gamma,x}) \leq |\mathcal{E}(f_{\gamma}) - \mathcal{E}(f_{\gamma,x})| + \mathcal{E}(f_{\gamma}).$$

Then the error $\mathcal{E}(f_{\gamma,x})$ satisfies the bound

$$\mathcal{E}(f_{\gamma,x}) \leq E(\gamma) + \sigma_\rho^2$$

and therefore, subtracting $\sigma_\rho^2$ from both sides and using (4) for $f = f_{\gamma,x},$

$$\int_X (f_{\gamma,x} - f_\rho)^2 \leq E(\gamma).$$

This proves the first part of the Main Result. Note that this is actually a family of bounds parameterized by $t < 2$ and $0 < \theta < 1$ and depends on $m, \delta, K$ and $f_\rho.$

For a point $\gamma > 0$ to be a minimum of $E(\gamma) = \mathcal{J}(\gamma) + \mathcal{A}(\gamma)$ it is necessary that

$$\mathcal{J}'(\gamma) + \mathcal{A}'(\gamma) = 0.$$ Taking derivatives, we get

$$\mathcal{J}'(\gamma) = -64M^2v^*(m, \delta)C_K \frac{\gamma + C_K}{\gamma^3}$$

and

$$\mathcal{A}'(\gamma) = \theta \gamma^{\theta-1}||L_K^{-\theta/2}f_\rho||^2.$$ Thus the solutions of $\mathcal{A}'(\gamma) + \mathcal{J}'(\gamma) = 0$ are those of

$$\theta \gamma^{\theta+2}||L_K^{-\theta/2}f_\rho||^2 - 64M^2v^*(m, \delta)C_K(\gamma + C_K) = 0$$

i.e. those of

$$\gamma^{\theta+2} - \frac{64M^2v^*(m, \delta)C_K}{\theta||L_K^{-\theta/2}f_\rho||^2} \gamma - \frac{64M^2v^*(m, \delta)C_K^2}{\theta||L_K^{-\theta/2}f_\rho||^2} = 0. \tag{5}$$

Using again Lemma 7, we obtain a unique solution $\gamma^*$ which is a minimizer of $E$ since $E(\gamma) \to \infty$ as $\gamma \to 0$ or $\gamma \to \infty.$ This finishes the proof of the Main Result.

Corollary 2 For every $0 < \delta \leq 1,$

$$\lim_{m \to \infty} E(\gamma^*) = 0.$$
Proof. The bound (3) shows that \( v^*(m, \delta) \to 0 \) when \( m \to \infty \). Now, equation (5) shows that \( \gamma^* \) is the only positive root of

\[
\gamma^{\theta+2} - Qv^*(m, \delta)\gamma - Qv^*(m, \delta)C_K = 0
\]

where \( Q = \frac{61M^2C_K}{\theta \| L_K^{-\theta/2}f_\delta \|^2} \). Then, by Lemma 7,

\[
\gamma^* \leq \max \left\{ \left( 2Qv^*(m, \delta) \right)^{\frac{1}{\theta+1}}, \left( 2Qv^*(m, \delta)C_K \right)^{\frac{1}{\theta+1}} \right\}
\]

from which it follows that \( \gamma^* \to 0 \) when \( m \to \infty \). Note that this implies that

\[
\lim_{m \to \infty} \mathcal{J}(\gamma^*) = \lim_{m \to \infty} (\gamma^*)^\theta \| L_K^{-\theta/2}f_\delta \|^2 = 0.
\]

Finally, it follows from equation (6) that

\[
(\gamma^*)^\theta - (Q\gamma^* + QC_K) \left[ \frac{v^*(m, \delta)}{(\gamma^*)^2} \right] = 0
\]

and therefore, that \( \left[ \frac{v^*(m, \delta)}{(\gamma^*)^2} \right] \to 0 \) when \( m \to \infty \). This, together with Theorem 3, shows that \( \lim_{m \to \infty} \mathcal{J}(\gamma^*) = 0 \). \( \square \)

6 Final Remarks

(1) This report can be seen as a solution of one instance of the Bias-Variance problem. Roughly speaking, the “bias” of a solution \( f \) coincides with our approximation error, and its “variance” with the sample error. Quoting [3],

A model which is too simple, or too inflexible, will have a large bias, while one which has too much flexibility in relation to the particular data set will have a large variance. Bias and variance are complementary quantities, and the best generalization [i.e. the smallest error] is obtained when we have the best compromise between the conflicting requirements of small bias and small variance.

As described in Section 3, Chapter II in [CS], the bias-variance problem amounts to the choice of a compact subspace \( \mathcal{H} \) of \( \mathcal{C}(X) \) over which \( \mathcal{E}_z \) is minimized. A too small space \( \mathcal{H} \) will yield a large bias while one too large will yield a large variance. Several parameters (radius of balls, dimension, etc.) determine the “size” of \( \mathcal{H} \) and different instances of the bias-variance problem are obtained by fixing all of them except one and minimizing the error over this non-fixed parameter. Our solution considers the ball of radius \( r = \| f_{\gamma,z} \|_K \) in \( \mathcal{H}_K \) and \( \mathcal{H} = \mathcal{F}_K(\mathcal{B}_r) \) (a space over which \( f_{\gamma,z} \) minimizes \( \mathcal{E}_z \)). The number

14
$r$ is our replacement of the VC-dimension. Since $\gamma$ is inversely proportional to $r$, large $\gamma$ corresponds to large bias or approximation error and small $\gamma$ to large variance or sample error.

Failing to find a good compromise between bias and variance leads to what is called underfitting (large bias) or overfitting (large variance). As an example, consider the curve $\mathcal{C}$ in the figure below with the set of sample points and assume we want to approximate that curve with a polynomial of degree $d$ (the parameter $d$ determines in our case the dimension of $\mathcal{H}$). If $d$ is too small, say $d = 2$, we obtain a curve as in (a) in the figure, which necessarily “underfits” the data points. If $d$ is too large, we can tightly fit the data points but this “overfitting” yields a curve as in (b).

![Diagram showing underfitting and overfitting](image)

For more on the bias-variance problem see [3], the above mentioned section in [CS], [6], and the references in these papers. Note, however, that the literature on this problem is vast and we have only touched on it.

(2) One could interpret the main estimates in this paper in terms of algorithms for approximating solutions of integral equations by Monte Carlo methods. But for most algorithms in the theory of integral equations the points $x_i$, $i = 1, \ldots, m$, are not randomly chosen but taken for example as a set of lattice points of a domain $X \subset \mathbb{R}^n$ (this would correspond to active learning in the learning theory literature). Now one might take $\rho_X$ as Lebesgue measure and the $x_i$ from a uniform grid of points. The theory in our previous paper [CS] should permit modifications to deal with this situation and our main result here as well.

(3) Our work can be interpreted in the area of statistics known as regularized nonparametric least squares regression. A general reference for this area is the book by Sara van de Geer [14]. Besides the references in this book, the papers [2, 1, 8, 9] are also related to our work. A result somewhat similar in spirit to our main result appears in [11, 12]. Here a function $E(m, n)$ is exhibited bounding the error in terms of the number $m$ of examples and the number $n$ of basis functions in a space of Gaussian radial basis functions and it is shown that, for each $m \in \mathbb{N}$, $E(m, n)$ has a unique minimizer $n^*$. 
References

Addenda. Corrections to [CS].

(1) A regularity hypothesis on measure $\rho_X$ on $X$ requiring every open set on $X$ to have positive measure is needed for our extension of Mercer Theorem and its applications. This is a mild hypothesis since open sets with zero measure can be deleted from $X$ with no harm.

(2) In connection with the matrices associated to a Mercer kernel, the “positive definite” condition should be relaxed to “positive semidefinite.”
